Abstract

Aim: The present study was designed to evaluate the safety of seabuckthorn (SBT) (*Hippophae rhamnoides* L. Elaeagnaceae) leaves added in the diet of Japanese quail.

Materials and Methods: A total of ninety quail chicks were randomly divided into 2 groups and fed a standard quail chick mash added with or without 2% SBT leaf powder (Group SX), and a standard quail chick mash (Group CX, control) for 21 days. Six animals from each group were randomly sacrificed at 7, 14 and 21 day post feeding. Blood and tissue samples were collected for biochemical and histopathological studies.

Results: The inclusion of SBT in quail diet did not affect the weekly body weights, clinical signs or mortality among the birds. The serum biochemical parameters like alanine transaminase, total protein, albumin, cholesterol and uric acid values in SBT treated group were found at par with those in the control group. Gross and histopathological studies of various internal organs such as liver, kidneys, heart, spleen, proventriculus, small intestine, bursa and thymus did not reveal any significant lesions in the tissue sections. However, proliferation of lymphoid tissue was a prominent finding noted in different lymphoid organs.

Conclusion: In conclusion, the addition of seabuckthorn leaf powder at 2% level in the diet of Japanese quail was found to be safe and it can be used as a feed additive.

Keywords: biochemical changes, Japanese quail, pathology, seabuckthorn

Introduction

Seabuckthorn (*Hippophae rhamnoides*) (SBT) is a naturally growing shrub that is native to Eastern Europe and Asia and is found in the high altitudes of Indian Himalayan region. It is not only adaptable to high altitude region, but its leaves and fruit also contain abundant of nutrients. SBT is widely used in traditional medicine for the treatment of cardiovascular diseases, flu, mucosal injuries, skin disorders, hepatotoxicity and hypoglycemia [1,2,3]. All parts of this wonder plant are considered to be a good source of a large number of bioactive compounds, including carotenoids, tocopherols, sterols, flavonoids, lipids, vitamins, tannins, minerals, etc. which contributes to its wide usage as a natural antioxidant [3,4,5]. SBT leaves are rich in flavonoids, tannins and triterpenes [6] and possess antioxidant and immunomodulatory [7], anti-stress and anti-inflammatory activity [8]. SBT byproducts were also found to ameliorate the toxic effect of different toxins in poultry feed [9,10]. Studies showed that the leaves and fruit residues of SBT could be used to feed poultry

and livestock without the accumulation of toxins, and that the feed also had a stimulating effect on growth and performance of poultry and livestock [11, 12]. Guan et al [13]. found that SBT fresh leaves are rich in total carotenoids (26.3 mg/100g) and total chlorophyll (98.8 mg/100g), an indicator of quality for green vegetables; whereas dried leaves still contained large quantities of bioactive compounds comparable to commonly consumed vegetables. Hippophae leaves also contain significant amounts of proteins (20.7%), amino acids (0.73% lysine, 0.13% methionine and cystine) [12], minerals (Ca, Mg and K), folic acid, catechins, esterified sterols, triterpenols and isoprenols [13,14]. According to Kumar et al. [15], the tannins hippo-phaenins A and B were isolated from SBT leaves.

Poultry farming is an important industry in most of the provinces and regions of India. The poultry industry has made rapid strides in last two decades in India which has been possible due to good breeds of birds, balanced diet, good health care and management practices. Addition of seabuckthorn on a routine basis in poultry diet would depend upon its beneficial effects on growth response and immunomodulation. In recent years less attention has been paid to the use of SBT as a poultry and livestock feed, therefore determination of

the safety and nutritive value of SBT will provide valuable information that can be used to promote its use as livestock and poultry feed additive [12].

Present study was planned for the safety evaluation of SBT leaf powder in the feed of Japanese quail on the basis of clinic-pathological study so that it can be promoted as a feed additive in the poultry feed.

Materials and Methods

Ethical approval: The animal care and experimental protocol was approved by institutional animal ethical committee as per CPCSEA guidelines.

Experimental birds and their management: Ninety, day-old Japanese quail chicks belonging to the same breeding flock were purchased from Central Poultry Development Organization, Chandigarh, India. Prior to arrival of day-old chicks, the experimental room, cages, trays and cage stands were thoroughly cleaned with water, 2.5% phenol, dried under sunlight, and flamed with dry heat using a blowlamp. The room was fumigated with formaldehyde gas, just one day prior to arrival of quail chicks. The waterers and feeders were cleaned daily with 5% KMnO₄ solution throughout the experiment.

Plant material: Seabuckthorn (*H. rhamnoides* L.) leaves were collected from the orchard of Krishi Vigyan Kendra (KVK), CSK HP Krishi Vishwavidyalaya, Kukumseri, District Lahaul, Himachal Pradesh, India at an altitude of 8866 feet from mean seal level. Fresh leaves were dried under shade in a clean, dust free environment and ground to fine powder. The plant material was also submitted for biochemical estimation to Department of Biotechnology, Amrita University, Kollam, Kerala, India. The sample was found to contain with flavonoids such as quercetin (0.020%), kaempferol (0.015%) and isorhamnetin (0.15%) using High Performance Liquid Chromatography (HPLC).

Feeding schedule: The quail chicks were fed dietary treatments (Quail mash procured from Department of Animal Nutrition, College of Veterinary Scienc, CSK HP Krishi Vishwavidyalaya, Palampur amended with

the appropriate additives) from day 1 until the end of the experiment. Feed was autoclaved before feeding or mixing SBT powder. Pre-boiled drinking water was provided to the chicks during the experiment. Feed and water were available for *ad libitum* consumption.

Experimental design: Ninety, day-old Japanese quail chicks were randomly divided into 2 equal groups *i.e.* control group (CX) and SBT (at the level of 2% in diet) treated group (SX) with 45 birds in each. Three replicate pens of 15 quail chicks were assigned to each group. The dietary treatment was started from day 1 and continued up to 21 days for the study of growth response, clinico-biochemical parameters and the gross and histopathological studies.

Clinical signs, growth rate, mortality and serum biochemistry: Birds from each group were closely observed, at least thrice daily, for the development of clinical signs and mortality, if any. In order to evaluate the effect of SBT leaf powder on the weekly body weights, 9 randomly selected quail chicks (three per replicate) from each group were weighed on 0, 7, 14 and 21 day post feeding (DPF). After weighing, 2 ml of blood was collected via cardiac puncture from 6 randomly selected birds from each group on 7, 14 and 21 DPF for the estimation of serum alanine transaminase (ALT), total serum proteins (TSP), albumin, cholesterol and uric acid. All the biochemical estimations were done using diagnostic kits (Reckon Diagnostics Pvt. Ltd., Baroda, India) in a Blood Chemistry Analyzer (RA-50 Auto Chemistry System) as per the manufacturer's recommendations.

Gross pathology and histopathology: Six randomly selected quail chicks (two per replicate) were euthanized from each group at 7, 14, and 21 DPF and also examined for gross lesions, if any. Representative tissue samples were collected from liver, kidneys, spleen, heart, bursa, proventriculus etc. in 10% neutral buffered formalin for histopathological studies. Fixed tissues were trimmed, embedded in paraffin, sectioned at 3-5 μ m, and stained with haematoxylin and eosin [16].

Figure-2. Photomicrographs of liver, kidney, spleen and bursa.

a. SBT group (SX) bird showing normal histological appearance liver.
 b. SBT (SX) group showing normal renal architecture
 c. SBT group (SX) bird showing active lymphoid proliferation in spleen.
 d. SBT (SX) group showing enlarged bursal follicles (arrow)

Statistical analysis: Data generated in the present study were subjected to statistical analysis by paired student's *t*-test for calculation and comparison of mean values between the groups at various intervals. A level of significance was based on the 95% level of probability. The results were expressed as mean \pm standard error (SEM).

Results

Clinical sign, mortality and growth response: In SBT leaf powder fed group (SX) no clinical signs and mortality was recorded throughout the experiment. The SBT treated birds showed almost equal weekly body weight in comparison to those in the control birds. (Figure-1).

Biochemical parameters: The results of the various biochemical parameters at different intervals are presented in Table-1. No significant difference was observed in the values of serum ALT, total protein, albumin and uric acid of SBT treated group (SX) in comparison to control group (CX) at different intervals of the experiment. However, serum cholesterol values were found to be non-significantly higher in SBT treated group at various intervals of the study.

Gross pathology: In the liver and kidneys, mild swelling and paleness were the only gross changes were recorded in few birds of group SX at various intervals. No major gross finding was observed in other organs.

Microscopic pathology

Liver: Liver sections in group SX chicks revealed mild to moderate congestion and vacuolar changes at various intervals (Figure-2a) of the experiment. These changes were comparable with those in the group CX birds.

Kidneys: The sections of the kidneys revealed proximal convoluted tubules (PCTs) with clear brush bordered epithelium, distal convoluted tubules (DCTs) and glomeruli with clearly visible capsular spaces in the renal cortex. The medullary region of the kidneys showed collecting tubules, collecting ducts and thick and thin segments of loops of Henle with normal epithelium. In SBT treated group mild to moderate congestion was recorded along with a slight accumulation of hyaline material in the tubular epithelial cells at various intervals of the experiment. However it, comparable to those in the control birds (Figure-2b).

Heart: The heart sections of SBT treated group chicks did not reveal any significant change at any interval of the experiment and comparable to those in the control group. The muscle fibers appeared normal with striations intact and oval shaped nuclei throughout the experiment.

Spleen: In group CX splenic red and white pulp were distinct and normal in proportion. Spleen sections of group SX showed mild reticuloendothelial and marked lymphoid cell hyperplasia at various intervals (Figure-2c). In addition, mild hyperplastic changes in reticuloendothelial cells lining the periarterial sheath was also noted at 21 DPF.

Bursa: Normal bursa with well distinct lymphoid tissue was found in both groups. However, at 21 DPF the follicular size in group SX was found to be larger along with plenty of lymphoid element. (Figure-2d) in comparison to those in the control (CX).

Thymus: In group SX, thymus was found comparable to control group (CX) at all the intervals with normal lymphoid tissue.

Proventriculus: The control group (CX) showed mild periductal congestion whereas lymphoid nodules in the subepithelial tissue and in the proventricular gland were normal with abundant lymphoid tissue. In group SX, mild periductal congestion along with dilatation of the duct of proventricular glands containing plenty of cellular debris and mucus were the characteristic findings at 14 DPF. However, lymphoid tissue in the proventricular gland was abundant and comparable to those in the control.

Intestine: In group CX, duodenum revealed tall cylindrical villi with well intact epithelium admixed with a few goblet cells were seen. The lymphoid element in the caecal tonsil was comparable to those in control with normal villus structure. In group SX, except for mild swelling and hyperplastic changes in the lining epithelial cells of villi in the duodenum at 14 DPF, no other significant change was observed throughout the period of study.

Discussion

Results of the present study showed that addition of SBT leaf powder in feed produced no adverse effect on the growth response and survivability of the treated birds. Earlier, Chen et al. [17] supplemented the basal diet of broiler chicken with 0.25%, 0.5% and 1% SBT leaves, respectively and found that 0.5% SBT leaves were beneficial to the growth performance in Arbor Acres broilers and 1% SBT leaves improved absorption of the calcium and phosphorous and the deposition of calcium. Sharma et al. [18] also reported that addition of SBT cake in poultry feed up to 30% replacement of crude protein showed better growth response and feed conversion ratio. In the present study, different biochemical parameters favored the fact that addition of SBT leaf powder in feed produces no harmful effects on the liver, kidneys and other body organs. The mean total serum albumin, total protein, ALT and uric acid concentration were found more or less similar to CX during the experiment. Cholesterol concentration in SBT group showed non significantly higher serum values in comparison to control group. This finding is also supported by gross and histopathological findings of liver with mild paleness and enlargement in SBT group which might be due to the presence of fat vacuoles in the hepatocytes as detected by histopathologically. This finding further suggested that SBT might have stimulated the cholesterol biosynthesis. Igarashi et al. [19] also reported that in the rats given cholesterol-free diet the level of serum triacylglycerols in the quercetin group (seabuckthorn flavonoid) was significantly higher as compared to those in the control. Histopathologically, the tissue architecture at various organs in SBT treated group was found comparable to those in the control except for the proliferation of lymphoid structure in different lymphoid organs. This proliferation of lymphoid element in different lymphoid tissue like spleen, bursa and caecal tonsils indicated toward some immunostimulatory potential

of SBT leaves in quail. In an earlier study [3] SBT leaf and fruit extract found to stimulate lymphocyte proliferation *in vitro* without any kind of stimulant. Few researchers also demonstrated the hepatoprotective effect of SBT leaves extract in rats during CCl₄ induced hepatic damage [1,20] and against aflatoxicosis in poultry birds [10].

Since the SBT leaves, containing high crude protein, amino acid, calcium and phosphorous, they have certain advantages for basic materials to formulate feed for livestock and poultry. In the development of formula food from SBT more attention should be paid to the selection of food components, conducting tests and consideration of production and marketing, etc. The body weights of livestock and poultry were increased [21,22] considerably after feeding with leaves, seeds and fruit residues of SBT. The experiment showed that the body weights of piglets were increased 9.38% after 60 days feeding with SBT and the amount of milk produced by goats was also increased 5.74% after 40 days. The rate of laying eggs and the number of eggs were also increased 10.3% and 28.1% for 2-year-old hens. The weight of chickens increased 5.74% and that of hens 7.81% after feeding with SBT leaves and fruit residues for 56 days [21,22]. The leaves and fruit residues of SBT can be treated by such methods as silaging, aminating or basification in order to decrease the content of crude fiber, increase the digestibility of crude fiber and dainty for livestock and poultry. Research in the development of formula food, pre-food and food additives of SBT should provide for conditions of great potential and markets [21].

Conclusion

Addition of seabuckthorn leaf powder at 2% level in poultry feed was found to be safe for Japanese quail on the basis of growth response, biochemical and the gross and histopathological studies. Moreover, it has some immunostimulatory potential resulting in proliferation of lymphoid tissues in various lymphoid organs.

Authors' contributions

VP, RKA and RDP designed the study. VP collected the research material and done the whole bench work. RKA had given guidance during the study. VP, RKA, and RDP drafted and revised the manuscript. All the authors had read and approved the final manuscript.
